Detecting termination using size-change in parameter values

Masters Thesis in Computer Science

David Wahlstedt Supervisor: Thierry Coquand

30 October 2000

Abstract

We present a method to automatically detect termination in a strict, first order functional language. This is a first step towards an application of the method on Agda [Agda]. The method is based on a paper of Neil Jones et al [Jones 00].

To any program, seen as a set of equations defining recursive functions, we associate a graph of calls, whose arcs are themselves graphs. These graphs describe for each call the size relations between the formal parameters and the actual parameters.

The termination condition can then be stated in terms of these graphs: each infinite path in the graph of calls must contain an infinitely decreasing thread.

What is surprising is that this condition can then be decided by a fully automatic algorithm. The method is quite general, and it is not dependent of auxiliary requirements like for example lexicographically ordered parameters. We have written a small Haskell prototype and tested this method on some examples.

1 Introduction

1.1 Background

There are several reasons for studying automated termination detection techniques: One general field of application is as an aid for debugging programs, e.g. finding loops that may cause non-termination. More issues motivating automated termination detection – e.g partial evaluation – can be found in [Jones 00]. An algorithm has been introduced for the functional programming paradigm by [Jones 00] which is inspired from [Sagiv 91], a termination detection algorithm for prolog/datalog programs.

1.2 Motivation for this work

In Agda [Agda], notations of functional programming are used for representing proofs: case expressions correspond to case analysis, let expressions represent local definitions/lemmas, and constructors represent introduction rules for inductive definitions. It is then natural to represent inductive proofs by using case expressions and recursive definitions. However for this proof to be correct, the recursion has to be well-founded, i.e. recursive calls have to be decreasing with respect to a well-founded ordering. The algorithm of [Jones 00] provides a uniform method to ensure what may be called "structural well-founded termination", and this can be applied to Agda's functional representation of proofs.

Our contribution is a detailed presentation of the algorithm of [Jones 00], suitably adapted to programs using case notation. We limit ourselves to the data type of unary natural numbers, but we believe that the method can be extended to the general case of data types used in Agda.

1.3 Headlines of the algorithm

Assume we want to define the subtype relation in a Haskell-like language given a subtype function subA for some previously defined type A, as follows:

```
subA :: A -> A -> Bool

data T = Prim A | Arrow T T

sub :: T -> T -> Bool
sub (Prim a1) (Prim a2) = subA a1 a2
```

```
sub (Arrow t1 u1)(Arrow t2 u2) = sub t2 t1 && sub u1 u2
sub _ _ = False
```

Provided all elements of T are well-founded, we know that for instance Arrow t1 u1 is greater than both t1 and u1, because t1 and u1 are subterms of Arrow t1 u1. Using this information we can extract size-change relations between the actual and formal parameters in sub summarised in what we will call a "size-change graph", a bipartite graph with labelled arcs. In our diagrams of these graphs an arc (or an undirected edge) between nodes i and j denotes that j'th formal parameter is strictly greater (or greater or equal) than the i'th actual parameter. For each function application defined in the body of sub we extract a size-change graph in this manner illustrated below:

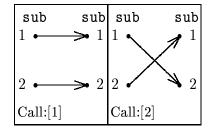

Figure 1: The size-change graphs extracted from sub.

From the figure we see that any infinite sequence of these graphs must contain an infinite sequence of strictly decreasing adjacent arcs constituting what we will call an *infinitely descending thread*. The first (and also the second) argument decreases infinitely often. Hence an infinite computation is not possible for any well-founded input, and the program must terminate.

The surprising fact is that the property stating that any infinite composition contains an argument that decreases (formally) infinitely often is decidable. Furthermore the algorithm is relatively simple:

The termination detection method of [Jones 00] consists of two phases. The first is to derive a set of size-change graphs from the program we want to check. For each function definition, to each function application in the program, a size-change graph is associated that reflects the known size relations between the formal parameters of the function definition and actual parameter values of the application. The second phase of the analysis then decides if every infinite computation of the program gives an infinitely decreasing sequence with respect to the size-change graphs: We first compute all possible finite compositions, and then we check that every idempotent graph contains a decreasing argument (i.e. an arrow from i to i). In this

case there is only one idempotent graph. For that graph both arguments are decreasing.

The concept of size-change graphs will be formally described in Section 3. The termination criterion will be treated in detail in Section 4. Our language and its semantics is defined in Section 2, and in Section 3.3 we connect the programming language with the termination detection criterion.

1.4 Some examples

Earlier techniques for approximating size-change termination have auxiliary requirements on the order of the parameters, etc. In [Abel 98], a lexicographic ordering is required for termination to be detected. The tuple of formal parameters must be strictly greater than any tuple of actual parameters of any call, both direct and indirect recursive. If there is a lexicographic ordering of the components of the tuples such that the above condition holds, the program must terminate. This method is relatively strong and also fast, but there are cases where it fails as we will see below.

The method of [Jones 00] contains the lexicographic ordering termination of [Abel 98], for instance it detects termination of the Ackermann function, that meets these requirements:

$$\begin{array}{l} \mathtt{ack}(\mathtt{x}_1,\mathtt{x}_2) = \mathtt{case} \ \mathtt{x}_1 \ \mathtt{of} \\ 0 \to \mathtt{S}(\mathtt{x}_2) \\ \mathtt{S}(\mathtt{x}_1{}') \to \mathtt{case} \ \mathtt{x}_2 \ \mathtt{of} \\ 0 \to \mathtt{ack}(\mathtt{x}_1{}',\mathtt{S}(\mathtt{0})) \\ \mathtt{S}(\mathtt{x}_2{}') \to \mathtt{ack}(\mathtt{x}_1{}',\mathtt{ack}(\mathtt{x}_1,\mathtt{x}_2{}')) \end{array}$$

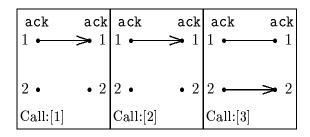

Figure 2: The size-change graphs extracted from ack.

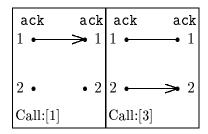

Figure 3: The set of all distinct compositions of graphs of ack.

The following example is a translation from a similar program in [Abel 98]. The program outputs a list of elements interleaved from the lists that are the two arguments. In our language the program becomes an addition program adding up ones from every other argument giving their sum as output. The program terminates and does so by the algorithm of [Jones 00], but it does not meet the requirement of lexicographical ordering of parameter tuples, so this example was used in [Abel 98] to show a shortcoming of their algorithm – it cannot detect termination due to swapped parameters.

$$\mathtt{add}(\mathtt{x}_1,\mathtt{x}_2) = \mathtt{case} \ \mathtt{x}_1 \ \mathtt{of} \ 0 \ o \ \mathtt{x}_2 \ \mathtt{S}(\mathtt{x}_1') \ o \ \mathtt{S}(\mathtt{add}(\mathtt{x}_2,\mathtt{x}_1'))$$

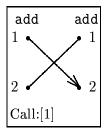

Figure 4: The size-change graphs extracted from add.

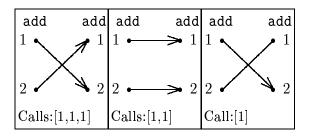

Figure 5: The set of all distinct compositions of graphs of add.

A less artificial example of swapped parameters is the subtype function of Example 1.3.1 above, which unfortunately can not yet be implemented in our language due to lack of user-definable type constructors.

The following example from [Abel 98] illustrates how [Jones 00] method applied to a non-terminating program give a useful output that indicates which loops (sequence of calls) may cause non-termination. In Abels example this program shows that the lexicographical ordering requirement is violated by an indirect call f, g, g, f.

$$\begin{split} \mathbf{f}(\mathbf{x}_1,\mathbf{x}_2) &= \mathsf{case} \ \mathbf{x}_1 \ \mathsf{of} \\ 0 \to 0 \\ S(\mathbf{x_1}') \to \mathsf{case} \ \mathbf{x}_2 \ \mathsf{of} \\ 0 \to 0 \\ S(\mathbf{x_2}') \to h(\mathbf{g}(\mathbf{x_1}',\mathbf{x}_2),\mathbf{f}(S(S(\mathbf{x}_1)),\mathbf{x_2}')) \\ \mathbf{g}(\mathbf{x}_1,\mathbf{x}_2) &= \mathsf{case} \ \mathbf{x}_1 \ \mathsf{of} \\ 0 \to 0 \\ S(\mathbf{x_1}') \to \mathsf{case} \ \mathbf{x}_2 \ \mathsf{of} \\ 0 \to 0 \\ S(\mathbf{x_2}') \to h(\mathbf{f}(\mathbf{x}_1,\mathbf{x}_2),\mathbf{g}(\mathbf{x_1}',S(\mathbf{x}_2))) \\ h(\mathbf{x}_1,\mathbf{x}_2) &= \mathsf{case} \ \mathbf{x}_1 \ \mathsf{of} \\ 0 \to \mathsf{case} \ \mathbf{x}_2 \ \mathsf{of} \\ 0 \to 0 \\ S(\mathbf{x_2}') \to h(\mathbf{x}_1,\mathbf{x}_2') \\ S(\mathbf{x_1}') \to h(\mathbf{x}_1',\mathbf{x}_2) \end{split}$$

The algorithm of [Jones 00] is PSPACE-hard in program size, which may appear to be a problem. Here follows an example program containing nine graphs. The fixed point iteration giving all finite compositions give 565 distinct graphs. To find out that this program is not terminating by the algorithm, we have to find and idempotent graph that has no decreasing argument.

$$\begin{array}{c} f_0(x_1,x_2,x_3,x_4,x_5) = case \; x_1 \; of \\ 0 \to 0 \\ S(x_1^{'}) \to case \; x_4 \; of \\ 0 \to 0 \\ S(x_4^{'}) \to f_1(x_2^{'},x_2,x_4^{'},x_4,S(S(x_5))) \\ f_1(x_1,x_2,x_3,x_4,x_5) = case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_2(x_2,x_1,x_3,x_4,x_5^{'}) \\ f_2(x_1,x_2,x_3,x_4,x_5) = case \; x_3 \; of \\ 0 \to 0 \\ S(x_3^{'}) \to case \; x_4 \; of \\ 0 \to case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_3(x_1,x_2,x_3^{'},x_4,x_5^{'}) \\ S(x_4^{'}) \to case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_5(x_1,x_2,x_3,x_4^{'},x_5^{'}) \\ f_3(x_1,x_2,x_3,x_4,x_5) = case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_4(x_1,x_2,x_4,x_3,x_5^{'}) \\ f_4(x_1,x_2,x_3,x_4,x_5) = case \; x_1 \; of \\ 0 \to 0 \\ S(x_1^{'}) \to case \; x_2 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_3(x_1^{'},x_2,x_3,x_4,x_5^{'}) \\ S(x_2^{'}) \to case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_2(x_1,x_2^{'},x_3,x_4,x_5^{'}) \\ f_5(x_1,x_2,x_3,x_4,x_5) = case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_6(x_2,x_1,x_3,x_4,x_5^{'}) \\ f_6(x_1,x_2,x_3,x_4,x_5) = case \; x_5 \; of \\ 0 \to 0 \\ S(x_5^{'}) \to f_0(x_1,x_2,x_4,x_3,x_5^{'}) \\ \end{array}$$

2 Language, syntax, semantics

2.1 Language

We consider a strict first-order functional language:

 $\begin{array}{lll} \mathbf{p} & \in Prog & , & \text{the set of programs} \\ \mathbf{def} & \in Fundef & , & \text{the set of function definitions} \\ \mathbf{f} & \in FunName & , & \text{the set of function names} \\ \mathbf{e} & \in Exp & , & \text{the set of expressions} \\ \mathbf{t} & \in Term & , & \text{the set of non-case expressions} \\ \mathbf{x}, \mathbf{y} & \in Var & , & \text{the set of variable names} \end{array}$

Programs in abstract notation are defined inductively as follows:

- A program p in this language is a list of definitions def_1, \ldots, def_m .
- A function definition def_i is written $f_i(x_1, \ldots, x_{ar(f_i)}) = e_{f_i}$, where all the formal parameters $x_1, \ldots, x_{ar(f_i)}$ are distinct and $ar(f_i)$ denotes the arity of function f_i . The expression e_{f_i} is called the function body of f_i .
- An expression e is either a term t or a case-expression case $x e_1 e_2$. To make it more comprehensible we will write case x of $0 \rightarrow e_1$ $S(x') \rightarrow e_2$.
- A term t is either a variable x, 0, or the successor of a term S(t) or a function application $f_i(t_1, \ldots, t_{ar(f_i)})$, where t_j are the actual parameters of the application.

We use variable names that are of the form \mathbf{x}_i or \mathbf{x}' , where \mathbf{x} is a variable name. We define $\mathbf{x}^{(k)}$ as follows:

$$x = x^{(0)}$$

 $x^{(k)'} = x^{(k+1)}$

Definition 2.1.1 (Free variables)

$$\frac{(\mathtt{y} = \mathtt{x}) \ or \ (\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{e}_1) \ or \ (\mathtt{y} \neq \mathtt{x}' \ \mathit{and} \ \mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{e}_2)}{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{y}}$$

$$\frac{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{y}}{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{t}}$$

$$\frac{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{t}}{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{S}(\mathtt{t})}$$

$$\frac{\exists \mathit{j.y} \ \mathit{free} \ \mathit{in} \ \mathtt{t}_j}{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{t}_j}$$

$$\frac{\exists \mathit{j.y} \ \mathit{free} \ \mathit{in} \ \mathtt{t}_j}{\mathtt{y} \ \mathit{free} \ \mathit{in} \ \mathtt{t}_i(\mathtt{t}_1, \ldots, \mathtt{t}_{\mathit{ar}(\mathtt{f}_i)})}$$

Definition 2.1.2 (Call) The pair $(f_i, f_j(t_1, \ldots, t_{ar(f_j)}))$ is a call for $f_i(x_1, \ldots, x_{ar(f_i)})$, if $f_j(t_1, \ldots, t_{ar(f_j)})$ is a sub-term of e_{f_i} .

Definition 2.1.3 (Syntactical size relation)

Define the relations > and \geq in $Exp \times Exp$ as follows:

$$\mathbf{x}_i > \mathbf{S}^l(\mathbf{x}_i^{(k)})$$
 if $k > l$
 $\mathbf{x}_i \geq \mathbf{S}^l(\mathbf{x}_i^{(k)})$ if $k = l$

From now on, we assume given a program p with the following property: The set of free variables in e_{f_i} is contained in $\{x_1, \ldots, x_{ar(f_i)}\}$, the formal parameters of f_i , for each i.

2.2 Semantics

A denotational semantics will be given for the language. D is the usual flat domain of natural numbers. If D_1 and D_2 are domains, let $[D_1 \to D_2]$ be the domain of continuous functions from D_1 to D_2 .

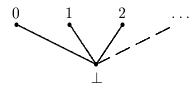

Figure 10: The semantic domain D

Let

$$\begin{split} D &= \mathbb{N} \cup \{\bot\} \\ VarEnv &= Var \to D \\ FunEnv &= \prod_{\mathbf{f} \in FunName} [D^{ar(\mathbf{f})} \to D] \\ \mathcal{E} &\in Exp \to [FunEnv \to [VarEnv \to D]] \\ \mathcal{P} &\in Prog \to [D^{ar(\mathbf{f}_1)} \to D] \end{split}$$

Syntactical constructors 0 and S are distinguished from the value constructors $\overline{0}$ and \overline{S} for elements of \mathbb{N} , to avoid confusion.

Definition 2.2.1 (Variable environments)

Given
$$\rho = (\mathbf{x}_1 = n_1, \dots, \mathbf{x}_k = n_k)$$
, then

$$\rho(\mathbf{x}_i) = \begin{cases} n_i & , & if \ i \in [1..k] \\ \bot & , & otherwise. \end{cases}$$

where $\rho \in VarEnv$.

Definition 2.2.2 (Predecessor function)

$$PRED(d) = \left\{ \begin{array}{ll} n & , & if \ d = \overline{S}(n), n \in \mathbb{N} \\ \bot & , & otherwise. \end{array} \right.$$

Definition 2.2.3 The tuple $(d_1, \ldots, d_n) \in D^n$ is well-defined if and only if all of its components are distinct from \perp .

Definition 2.2.4 The semantics of a program is defined as follows:

$$\begin{split} &\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{0}]\!]_{\rho} = \bar{\mathbf{0}} \\ &\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{S}(\mathbf{t})]\!]_{\rho} = \left\{ \begin{array}{l} \bot & , & if \ \mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{t}]\!]_{\rho} = \bot \\ \bar{\mathbf{S}} (\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{t}]\!]_{\rho}) & , & otherwise. \end{array} \right. \\ &\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{x}_{i}]\!]_{\rho} = \rho(\mathbf{x}_{i}) \\ &\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{x}']\!]_{\rho} = PRED(\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{x}]\!]_{\rho}) \\ &\mathcal{E}_{\boldsymbol{\phi}} [\![\mathbf{case} \ \mathbf{x} \ \text{of} \ 0 \rightarrow \mathbf{e}_{1} \ \mathbf{S}(\mathbf{x}') \rightarrow \mathbf{e}_{2}]\!] = 0 \end{split}$$

$$\begin{split} \mathcal{E}_{\boldsymbol{\phi}} \! [\![\operatorname{case} \, \mathbf{x} \, \operatorname{of} \, \mathbf{0} &\to \mathbf{e}_1 \ \ \, \mathbf{S}(\mathbf{x}') \to \mathbf{e}_2]\!]_{\rho} = \\ \left\{ \begin{array}{c} \bot & , \quad \!\! if \, \mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{x}]\!]_{\rho} = \bot \\ \mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{e}_1]\!]_{\rho} & , \quad \!\! if \, \mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{x}]\!]_{\rho} = \bar{\mathbf{0}} \\ \mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{e}_2]\!]_{\rho} & , \quad \!\! if \, \mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{x}]\!]_{\rho} = \bar{\mathbf{S}}(n), \, \, for \, some \, n \in \mathbb{N}. \\ \end{array} \right. \end{split}$$

$$\begin{split} \mathcal{E}_{\boldsymbol{\phi}} \! \big[\!\![\mathbf{f}_i(\mathbf{t}_1, \dots, \mathbf{t}_{ar(\mathbf{f}_i)}) \big]\!\!]_{\rho} &= \\ \left\{ \begin{array}{l} \boldsymbol{\phi}(\mathbf{f}_i)(\vec{d}) &, \quad \!\!\! if \quad \!\!\! \vec{d} \ \, is \ \, well\text{-}defined \\ \boldsymbol{\perp} &, \quad \!\!\! otherwise. \\ where \ \, \vec{d} &= (\mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{t}_1]\!]_{\boldsymbol{\theta}}, \dots, \mathcal{E}_{\boldsymbol{\phi}} \! [\![\mathbf{t}_{ar(\mathbf{f}_i)}]\!]_{\boldsymbol{\theta}}). \end{split} \right. \end{aligned}$$

Let $\tau_{i} \in [FunEnv \to [D^{ar(\mathbf{f}_{i})} \to D]]$ $\phi \mapsto ((d_{1}, \dots, d_{ar(\mathbf{f}_{i})}) \mapsto \mathcal{E}_{\phi} \llbracket \mathbf{e}_{\mathbf{f}_{i}} \rrbracket_{(\mathbf{x}_{1} = d_{1}, \dots, \mathbf{x}_{ar(\mathbf{f}_{i})} = d_{ar(\mathbf{f}_{i})})})$ $\tau \in [FunEnv \to FunEnv]$ $\phi \mapsto \mathbf{f}_{i} \mapsto \tau_{i}(\phi)$ $\Omega \in FunEnv$ $\mathbf{f}_{i} \mapsto (d_{1}, \dots, d_{ar(\mathbf{f}_{i})}) \mapsto \bot$

Let ϕ_{∞} denote the least fixed point of τ , a solution of $\tau(\phi) = \phi$:

$$\phi_{\infty} = \bigsqcup_{k=0}^{\infty} \{ \tau^k(\Omega) \}$$

Then,

$$\mathcal{P}[\![\mathbf{f}_1(\mathbf{x}_1,\ldots,\mathbf{x}_{ar(\mathbf{f}_1)})=\mathbf{e}_{\mathbf{f}_1},\ldots,\mathbf{f}_m(\mathbf{x}_1,\ldots,\mathbf{x}_{ar(\mathbf{f}_m)})=\mathbf{e}_{\mathbf{f}_m}]\!]=\phi_\infty(\mathbf{f}_1)$$

Thus, the first function in the list of definitions is considered as being the entry function of the program.

Lemma 2.2.1 If \mathbf{x}_i R \mathbf{t} , and $\mathcal{E}_{\phi}[\![\mathbf{t}]\!]_{\rho} \neq \bot$, where $R \in \{>, \geq\}$, then $\rho(\mathbf{x}_i)$ R $\mathcal{E}_{\phi}[\![\mathbf{t}]\!]_{\rho}$.

Proof: Assume $\mathbf{x}_i > \mathbf{t}$, and $\mathcal{E}_{\phi}[\![\mathbf{t}]\!]_{\rho} \neq \bot$. Then by Definition 2.1.3, we must have $\mathbf{t} = \mathbf{S}^l(\mathbf{x}_i^{(k)})$, where k > l. By assumption $\mathcal{E}_{\phi}[\![\mathbf{t}]\!]_{\rho} \neq \bot$, so $\rho(\mathbf{x}_i^{(k)}) \neq \bot$. So $\bot \neq \rho(\mathbf{x}_i) = m \geq k$. By Definition 2.2.4, $\mathcal{E}_{\phi}[\![\mathbf{S}^l(\mathbf{x}_i^{(k)})]\!]_{\rho} = \bar{\mathbf{S}}^l(\rho(\mathbf{x}_i) - k) = m - k + l < m$, because k > l. The proof for \ge is similar. \square

3 Call graph and size-change graphs

3.1 Size-change graphs

Definition 3.1.1 For a call $c = (f_i, f_j(t_1, \ldots, t_{ar(f_j)}))$ for $f_i(x_1, \ldots, x_{ar(f_i)})$, we define its size-change graph to be a bipartite graph,

$$G_c = ([1..ar(\mathbf{f}_i)], [1..ar(\mathbf{f}_i)], E)$$

where E is a set of labelled arcs: $E \subseteq [1..ar(\mathbf{f}_i)] \times \{>, \geq\} \times [1..ar(\mathbf{f}_j)]$, where $(m, R, n) \in E$ if and only if \mathbf{x}_m R \mathbf{t}_n , according to Definition 2.1.3.

We will say that a size-change graph (V, V, E) is decreasing if it contains an arc of the form (i, >, i) for some $i \in V$.

Definition 3.1.2 The set of size change graphs \mathcal{G}_p of a program p is defined as follows:

$$\mathcal{G}_{\mathbf{p}} = \{G_c \mid c \text{ is a call } (\mathbf{f}_i, \mathbf{f}_j(\mathbf{t}_1, \dots, \mathbf{t}_{ar(\mathbf{f}_j)})) \text{ in program } \mathbf{p} \}$$

Definition 3.1.3 By juxtaposition the relations >, \geq are composed as follows:

$$R_1 R_2 = \begin{cases} > &, & if R_1 \ is > or R_2 \ is > \\ \geq &, & otherwise. \end{cases}$$

Definition 3.1.4 Given arc sets

$$E_1 = \{(i_1, R_2, i_2) | i_1 \in [1..ar(\mathbf{f}_i)], i_2 \in [1..ar(\mathbf{f}_j)], R_2 \in \{>, \geq\}\}$$

and

$$E_2 = \{(i_2, R_3, i_3) | i_2 \in [1..ar(\mathbf{f}_j)], i_3 \in [1..ar(\mathbf{f}_k)], R_3 \in \{>, \ge\}\}$$

their composition E_1E_2 is defined as follows:

$$E_1E_2 = \{(i, RR', k) \mid (i, R, j) \in E_1, (j, R', k) \in E_2\}$$

Definition 3.1.5 Given size-change graphs $G = (V_1, V_2, E)$ and $H = (V_2, V_3, E')$ their composition is $GH = (V_1, V_3, EE')$, where EE' is the composition of arc sets E and E'.

3.2 Call graph

Definition 3.2.1 The call graph $\Gamma_{\mathbf{p}}$, of program $\mathbf{p} = \mathsf{def}_1, \ldots, \mathsf{def}_m$ is the directed graph (V, E) whose edges $E = \mathcal{G}_{\mathbf{p}}$, and whose vertices V = [1..m], the indices of the function names in \mathbf{p} . Each arc G_c of $\Gamma_{\mathbf{p}}$ has a source and a target $(s,t)G_c = (i,j)$ among the vertices $i,j \in V$, such that $(\mathbf{f}_i,\mathbf{f}_j(\mathbf{t}_1,\ldots,\mathbf{t}_{ar(\mathbf{f}_j)}))$ is a call in \mathbf{p} .

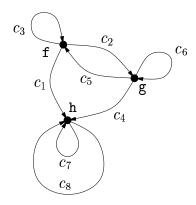

Figure 11: Call graph of Example 1.4.3. The arc c_i is associated to the i'th size-change graph in Figure 6.

Definition 3.2.2 A path

$$\gamma = G_{c_1}, G_{c_2}, \dots$$

in $\Gamma_{\mathbf{p}}$ is a sequence of arcs of $\Gamma_{\mathbf{p}}$ that may be finite or infinite, such that $t(G_{c_i}) = s(G_{c_{i+1}})$.

Definition 3.2.3 We define a thread of a path G_{c_1}, G_{c_2}, \ldots as a sequence of arcs

$$(m_1, R_2, m_2), (m_2, R_3, m_3), \ldots$$

such that (m_k, R_{k+1}, m_{k+1}) is an arc of $G_{c_{k+1}}$.

Definition 3.2.4 A path is said to be infinitely descending if and only if it contains a thread $\nu = (m_1, R_2, m_2), (m_2, R_3, m_3), \ldots$ such that there are infinitely many indices k where R_k is > in the thread ν .

Definition 3.2.5 Given

$$\gamma = G_1, G_2, \dots, G_k$$

a finite path of $\Gamma_{\mathbf{p}}$, let G_{γ} denote the composition:

$$G_1G_2\ldots G_k$$

Remark:

If (i_0, R, i_k) is an arc of G_{γ} , then γ has a thread

$$(i_0, R_1, i_1), (i_1, R_2, i_2), \ldots, (i_{k-1}, R_k, i_k)$$

such that $R = R_1 R_2 \dots R_k$. See Figure 12 below for an intuition.

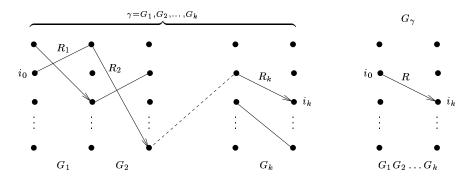

Figure 12: An example of a thread in γ and a corresponding arc in G_{γ} .

3.3 Properties of non-termination

Lemma 3.3.1 If $\mathcal{E}_{\phi}[\![\mathbf{e}]\!]_{\rho} = \bot$ and $\rho(\mathbf{x}) \neq \bot$ for all \mathbf{x} free in \mathbf{e} , then \mathbf{e} has a sub-term $\mathbf{f}_i(\mathbf{t}_1, \ldots, \mathbf{t}_{ar(\mathbf{f}_i)})$ such that $\mathcal{E}_{\phi}[\![\mathbf{f}_i(\mathbf{t}_1, \ldots, \mathbf{t}_{ar(\mathbf{f}_i)})]\!]_{\rho} = \bot$, and $\forall j.\mathcal{E}_{\phi}[\![\mathbf{t}_j]\!]_{\rho} \neq \bot$.

Proof:

By structural induction on e:

Assume $\mathcal{E}_{\phi}[\![\mathbf{e}]\!]_{\rho} = \bot$ and $\rho(\mathbf{x}) \neq \bot$ for all \mathbf{x} free in \mathbf{e} .

Then either:

- 1. e is a free variable x. This is not possible because $\rho(x) \neq \bot$ by assumption.
- 2. e is 0. This is obviously not possible.

- 3. e is S(t). Then apply Lemma 3.3.1 recursively on t.
- 4. e is case x of $0 \to e_1$ $S(x') \to e_2$. Then either:
 - (a) $\rho(\mathbf{x}) = \bot$. Impossible by assumption.
 - (b) $\rho(\mathbf{x}) = \overline{\mathbf{0}}$. Then apply Lemma 3.3.1 recursively on \mathbf{e}_1 .
 - (c) $\rho(\mathbf{x}) = \bar{\mathbf{S}}(d)$. Now, \mathbf{x}' may be free in \mathbf{e}_2 , but $\rho(\mathbf{x}') = d \neq \bot$. Hence we can apply Lemma 3.3.1 recursively on \mathbf{e}_2 .
- 5. e is $f_i(t_1, \ldots, t_{ar(f_i)})$. Then either:
 - (a) $\exists j \in [1..ar(\mathbf{f}_i)]. \mathcal{E}_{\phi}[\![\mathbf{t}_j]\!]_{\rho} = \bot$. Then apply Lemma 3.3.1 recursively on \mathbf{t}_j .
 - (b) $\forall j \in [1..ar(\mathbf{f}_i)].\mathcal{E}_{_{\boldsymbol{\phi}}}[\![\mathbf{t}_j]\!]_{_{\boldsymbol{\theta}}} \neq \bot$. Then Lemma 3.3.1 holds.

Since e is finite, case 5b is the only valid terminal alternative, which must apply to some sub-term of e. \square

Lemma 3.3.2 If $\phi_{\infty}(\mathbf{f}_{i_0})(\vec{d}_0) = \perp$, where \vec{d}_0 is well-defined, then there exists an infinite sequence

$$(c_1, \vec{d_1}), (c_2, \vec{d_2}), (c_3, \vec{d_3}), \dots$$

such that $(m, R, n) \in G_{c_{j+1}} \Rightarrow \vec{d_j}(m) \ R \ \vec{d_{j+1}}(n)$, where $\vec{d_j}$ is well-defined, for all $j \in \mathbb{N}$ and c_1 is a call for \mathbf{f}_{i_0} .

Proof: Assume $\phi_{\infty}(\mathbf{f}_{i_0})(\vec{d}_0) = \bot$ and \vec{d}_0 is well-defined. Then, according to Definition 2.2.4, $\mathcal{E}_{\phi_{\infty}}[\mathbf{e}_{\mathbf{f}_{i_0}}]_{\rho} = \bot$, where $\rho = (\mathbf{x}_1 = \vec{d}_0(1), \ldots, \mathbf{x}_{a_{i_0}} = \vec{d}_0(a_{i_0}))$. Recall that from the hypothesis of Section 2.1 that these are the only possible free variables of $\mathbf{e}_{\mathbf{f}_{i_0}}$. By Lemma 3.3.1, $\mathbf{e}_{\mathbf{f}_i}$ contains a call $c_1 = (\mathbf{f}_{i_0}, \mathbf{f}_{i_1}(\mathbf{t}_1, \ldots, \mathbf{t}_{ar(\mathbf{f}_{i_1})}))$ such that $\mathcal{E}_{\phi_{\infty}}[\mathbf{f}_{i_1}(\mathbf{t}_1, \ldots, \mathbf{t}_{ar(\mathbf{f}_{i_1})})]_{\rho} = \bot$, where $(\mathcal{E}_{\phi_{\infty}}[\mathbf{t}_1]_{\rho}, \ldots, \mathcal{E}_{\phi_{\infty}}[\mathbf{t}_{a_{i_1}}]_{\rho}) = \vec{d}_1$ and \vec{d}_1 is well-defined.

Now assume (m, R, n) is an arc of G_{c_1} . Then by Definition 3.1.1, we have \mathbf{x}_m R \mathbf{t}_n . This implies $\rho(\mathbf{x}_m)$ R $\mathcal{E}_{\phi_\infty}[\![\mathbf{t}_n]\!]_{\rho}$, by Lemma 2.2.1 because $\mathcal{E}_{\phi_\infty}[\![\mathbf{t}_n]\!]_{\rho} \neq \bot$. Since $\rho(\mathbf{x}_m) = \vec{d}_0(m)$ and $\mathcal{E}_{\phi_\infty}[\![\mathbf{t}_n]\!]_{\rho} = \vec{d}_1(n)$, we must have $\vec{d}_0(m)$ R $\vec{d}_1(n)$.

We have that $\phi_{\infty}(\mathbf{f}_{i_1})(\vec{d}_1) = \bot$, so we can proceed repeatedly in the same way to build the infinite sequence $(c_1, \vec{d}_1), (c_2, \vec{d}_2), (c_2, \vec{d}_3), \ldots$, with the properties stated above. \Box

Theorem 3.3.1 If every infinite path in Γ_p is infinitely descending, then p terminates on all well-defined input.

Proof: Assume $\mathcal{P}[\![p]\!](\vec{d_0}) = \bot$, where $\vec{d_0}$ is well-defined, and that all the infinite paths of Γ_p are infinitely descending. Then $\phi_{\infty}(\mathbf{f_1})(\vec{d_0}) = \bot$, so by Lemma 3.3.2 there exists an infinite sequence $s = (c_1, \vec{d_1}), (c_2, \vec{d_2}), (c_3, \vec{d_3}), \ldots$ such that $\vec{d_j}$ is well-defined and $c_{j+1} = (\mathbf{f}_{i_j}, \mathbf{f}_{i_{j+1}}(\mathbf{t_1}, \ldots, \mathbf{t}_{ar(\mathbf{f}_{i_{j+1}})}))$ is a call for $\mathbf{f}_{i_j}(\mathbf{x_1}, \ldots, \mathbf{x}_{ar(\mathbf{f}_{i_j})})$, where $i_0 = 1$, and whenever (m, R, n) is an arc of $G_{c_{j+1}}$, then $\vec{d_j}(m)$ R $\vec{d_{j+1}}(n)$.

Consider the infinite path $\gamma = G_{c_1}, G_{c_2}, G_{c_3}, \ldots$ By assumption γ is infinitely descending, so there is a thread of γ :

$$(m_l, R_{l+1}, m_{l+1}), (m_{l+1}, R_{l+2}, m_{l+2}), (m_{l+2}, R_{l+3}, m_{l+3}), \dots$$

starting at some index l in γ , such that $(m_j, R_{j+1}, m_{j+1}) \in G_{c_{j+1}}$, where there are infinitely many j such that R_j is >. Let us define $d_k = \vec{d_k}(m_k)$. Recall that by Lemma 3.3.2 we have $d_k R_{k+1} d_{k+1}$ with $R_{k+1} \in \{>, \geq\}$, for all $k \geq l$, and the set $\{j \mid R_{l+j} \text{ is } >\}$ is infinite. Hence $d_l, d_{l+1}, d_{l+2}, \ldots$ is an infinitely descending sequence in \mathbb{N} , which is absurd. \square

4 Termination detection algorithm

4.1 Ramsey's theorem

Definition 4.1.1 Let $[A]^2$ denote the set $\{B \subseteq A : |B| = 2\}$. By a "finite coloration" of $[A]^2$, we mean a function from $[A]^2$ into a finite set.

Theorem 4.1.1 Ramsey's theorem (Binary infinite version ¹) Given any finite colouring χ of $[\mathbb{N}]^2$, there exists an infinite subset T of \mathbb{N} , such that $[T]^2$ is monochromatic under χ (that is χ is constant on $[T]^2$).

Proof: Define the infinite sequence of infinite sets S_i as follows:

- i) Let $S_1 = \mathbb{N}$.
- ii) Having chosen S_i , choose $x_i \in S_i$ arbitrarily.
- iii) Let $T_j = \{u \in S_i \mid \chi(x_i, u) = j\}.$

Then $\{T_j \mid j \in \chi\}$ is a finite partition on $S_i \setminus \{x_i\}$. Choose S_{i+1} to be one of the infinite T_j . The sequence

$$X = x_1, x_2, x_3, \dots$$

¹The proof principally follows [Graham 80], page 16.

has the property that $\chi(x_i, x_j) = \chi(x_i, x_k)$ for all j > i, k > i, because if k > j, then $S_k \subseteq S_j$. Define a colouring χ^* of the singletons x_i

$$\chi^*(x_i) = c$$
 such that $\chi(x_i, x_j) = c$ for all $j > i$.

Then χ^* is a finite partition on the sequence X. So for some colour j, there must be an infinite sequence

$$X' = x_{i_1}, x_{i_2}, x_{i_3}, \dots$$

where i_1, i_2, i_3, \ldots are indices of elements in X, such that $\chi^*(x_{i_s}) = j$ for all s. But for any $1 \leq s < t$,

$$\chi(x_{i_s}, x_{i_t}) = \chi^*(x_{i_s}) = j.$$

Hence $[X']^2$ is monochromatic under χ . \square

4.2 Termination criterion using size-change graphs

Definition 4.2.1 Define S to be the set $\{G_{\gamma} \mid \gamma \text{ is a finite path of } \Gamma_{\mathfrak{p}}\}.$

Note that S is a finite set, because for each finite path γ in $\Gamma_{\mathbf{p}}$, where $G_{\gamma} = (V_1, V_2, E)$ there is only a finite set of possible configurations of E. And there is only a finite number of pairs of vertices in $\Gamma_{\mathbf{p}}$.

Theorem 4.2.1 All the infinite paths of $\Gamma_{\mathbf{p}}$ are infinitely descending if and only if for every $G \in \mathcal{S}$ such that $G^2 = G$ there is an arc (n, >, n) in G.

Proof: Suppose for every $G \in \mathcal{S}$ such that $G^2 = G$ there is an arc (n, >, n) in G. Choose an infinite path γ of Γ_p . We label the edges of γ as follows:

$$\gamma = G_1, G_2, G_3, \dots$$

Let γ_{ij} denote the finite section $G_i, G_{i+1}, \ldots, G_{j-1}$ of γ . Then we can define the function $\chi : [\mathbb{N}]^2 \to \mathcal{S}$ as: $\chi(i,j) = G_{\gamma_{ij}}$ for j > i.

 \mathcal{S} is a finite set, since there is only a finite number of possible size-change graphs of fixed arity. So χ is a finite colouring of $[\mathbb{N}]^2$. By Ramsey's Theorem, there is an infinite subset I of \mathbb{N} such that $[I]^2$ is monochromatic under χ . Consider the sorted sequence i_1, i_2, i_3, \ldots of elements of I. For each $j, k \in \mathbb{N}$ we have $\chi(i_j, i_k) = G_{\gamma_{i,i_k}} = G$ for some G in \mathcal{S} .

So γ can be sectioned $\gamma_{1i_1}, \gamma_{i_1i_2}, \gamma_{i_2i_3}, \ldots$, where each section $\gamma_{i_ji_k}$ has composition $G_{\gamma_{i_ji_k}}$ which is G. But then also $G^2 = G$, because $G_{\gamma_{i_1i_2}}G_{\gamma_{i_2i_3}} = G^2 = G_{\gamma_{i_1i_2},\gamma_{i_2i_3}} = G_{\gamma_{i_1i_2}}G_{\gamma_{i_2i_3}} = G$.

By assumption G has an arc (n, >, n) and then by the remark of Definition 3.2.5 each section $\gamma_{i_j i_{j+1}}$ has a thread

$$(m_0, R_1, m_1), (m_1, R_2, m_2), \ldots, (m_{q-1}, R_q, m_q)$$

where $m_0 = n = m_q, q = i_k - i_j$, and at least one of R_1, \ldots, R_q equals >, because $R_1 R_2 \ldots R_q = >$. Hence γ is infinitely descending.

For the reverse implication, assume $G = (V, V, E) \in \mathcal{S}$, and $G = G^2$, where there is no arc of the form (v, >, v) in G. Now suppose that every infinite path of Γ_p is infinitely descending, and from this deduce a contradiction.

We have $G \in \mathcal{S}$, so G is a composition G_{γ} of some finite path $\gamma = G_1, G_2, G_3, \ldots, G_q$ in $\Gamma_{\mathbf{p}}$. The left hand side set of vertices in G_1 which is V, is the same as the right hand side set of vertices in G_q , since G = (V, V, E).

Consider the infinite path $\gamma^{\omega} = \gamma, \gamma, \gamma, \ldots$ By assumption γ^{ω} is infinitely descending, and by Definition 3.2.4, γ^{ω} contains an infinitely descending thread $\nu = (m_0, R_1, m_1), (m_1, R_2, m_2), (m_2, R_3, m_3), \ldots$, starting in some arc of γ , then passing through γ infinitely often.

It is clear that ν passes through arcs of G_1 infinitely often. By the pigeon hole principle there must be an infinite subset of these arcs $(m_{i_j}, R_{i_j+1}, m_{i_j+1})$ of G_1 , such that $m_{i_j} = n$ for some $n \in V$, because V is a finite set.

Let us choose a finite section ν' of ν as follows: Choose the first arc of ν' to be $(m_{i_0}, R_{i_0+1}, m_{i_0+1})$. Let ν' be long enough to contain an arc $(m_l, >, m_{l+1})$, where $l \geq i_0$. Such an arc must exist because ν is infinitely descending. Choose the last arc of ν' to be an arc $(m_{i_t-1}, R_{i_t}, m_{i_t})$ of G_q (which is the last size-change graph in γ).

Hence ν' is a thread of some power γ^k of the same length kq. Hence $(m_{i_0}, >, m_{i_t}) = (n, >, n)$ must be an arc of G_{γ^k} . But $G_{\gamma^k} = G^k$, and $G = G^k$, because $G = G^2$. So the arc (n, >, n) must belong to G, which contradicts the assumption that G has no such arc. Hence all the infinite paths of Γ_p cannot be infinitely descending. \square

5 Remark on criterion by Jones et al.

The termination criterion presented by [Jones 00] is equivalent of the criterion presented in this paper. In [Jones 00] the graph G^+ denotes the union of arcs from all distinct powers of a size-change graph G. In our terminology their main theorem is:

All the infinite paths in Γ_p are infinitely descending if and only if for all $G \in \mathcal{S}$ such that G is self-composable there is an arc (i, >, i) in G^+ .

The latter is equivalent with the assertion: for all $G \in \mathcal{S}$ such that G is self-composable, there is n, such that G^n has an arc (i, >, i). It follows from the definition of G^+ , and we have simplified this by the statement that all G such that $G = G^2$ has an arc (i, >, i). This eliminates the need of defining G^+ and its generation in the termination detection algorithm. We give a direct proof of equivalence between these two results:

Theorem 5.0.2 For all $G \in \mathcal{S}$ such that $G^2 = G$, there is an arc (i, >, i) in G if and only if, for all $G \in \mathcal{S}$, such that G is self-composable, there is n, such that G^n has an arc (i, >, i).

Proof: Assume $(\forall G \in \mathcal{S} \text{ such that } G^2 = G).(i, >, i) \in G).$

Consider $H = (V, V, E) \in \mathcal{S}$. Let $Q = H^m$ such that $H^m = (H^m)^2$, $m \ge 1$. Such an m must exist because of Lemma 5.0.1 below. By assumption, since $Q = Q^2$, (i, >, i) belongs to Q. So we have m such that H^m contains the arc (i, >, i).

Assume now $\forall G \in \mathcal{S}$ such that G is self-composable, there is an (i, >, i) in some power G^n . Consider $H \in \mathcal{S}$, such that $H^2 = H$. We know by assumption that there is m such that H^m has an arc (i, >, i). But $H^m = H$, because $H = H^2$. So H has an arc (i, >, i). \square

Lemma 5.0.1 For any size-change graph G composable with itself, there is a natural number n, such that $(G^n)^2 = G^n$.

Proof: Since there is a finite number of size-change graphs for fixed arities, there must exist i < j such that $G^i = G^j$.

Then $G^i = G^{i+l}$ for j - i = l > 0. We have $G^i = G^{i+kl}$ for any k, m, and hence $G^{i+m} = G^{i+m+kl}$ for any k, m. We can choose k, m such that i + m + kl = 2(i + m). Then $G^{i+m} = (G^{i+m})^2$. \square

6 Conclusions

This algorithm appears to be both simpler and more powerful than the algorithm presented in [Abel 98]. One potential problem was efficiency. Although it it PSPACE-hard in the size of the program (see [Jones 00]), the worst cases arise when the size-change graphs contain many arcs with many swapped parameters. It seems that the algorithm is efficient enough for small programs with simple call structure. Functions with a large number of parameter values are rarely used, so the average time and space complexity seem to be quite good.

7 Future work

As termination analysis for Agda is the main motivation for our study of this algorithm, a task to be undertaken is the implementation of this system for Agda. First the algorithm should be generalised to fit a language with general data types. This can be achieved by using disjunct sums to distinguish constructors and Cartesian products for the arities of the constructors.

Furthermore higher order functions would be desirable to cover by the algorithm. We do not yet know how this should be accomplished. One possibility is that some higher order functions, like the "map"-function, for instance, can be transformed to first order form and then be checked for termination.

Another topic could be to use the method described in this paper in the "reverse direction" looking for infinitely increasing sequences, to ensure *productivity* for infinite structures. We don't know if this is a good idea, but it may be worth investigating. See [Giménez 95] for more reading about these issues.

A A small implementation

This section gives an example showing that the algorithm we present can be easily implemented in a straight-forward manner. In this work focus is not put on this implementation, but on the proof and understanding of the algorithm.

A.1 Main module

```
module Checker where
import Asyntax
import Parser
import Prettylatex
import Scgraph
import Callgraph
import Termcheck
import Examples
-- derive the set S:
finite_compos p = let gs = callgraph$parse p
                      in s gs
-- derive the set of size-change graphs:
graphs = callgraph.parse
-- derive all the self-composable graphs from S:
selfG p = let gs = graphs p
              in [ g | g@(G f f' _ _) <- s gs, f == f']
-- finds loops that may cause non-termination:
check p = let gs = graphs p
               non_sat = map showPath (find_nonterm gs)
               in if null non_sat then putStr "0k\n"
                                  else putStr(
                                        "Possible termination problems:\n" ++
                                        show non sat)
```

A.2 Termination detection module

module Termcheck where

```

Finding possible non-termination:
Checker> check fgh
Possible termination problems:
["f-f:[]*[2,6,5,3]*","g-g:[]*[5,3,2,6]*"]
```

{-- Neil Jones et al. example of hard time and space complexity:

This example was used in [Jones00] to show PSPACE-hardness of the algorithm. The hard part is to generate all the finite compositions of size-change graphs - the more swappings the harder.

```
1: X := not X
2: if Y goto 5 else 3
3: Y := not Y
4: if X goto 2 else 3
5: X := not X
6: Y := not Y
```

Each line is a function that calls another function(line). The parameters are all the variables in the program, and their boolean inverses, plus one extra argument z. We always have a call from the last line to the first. From each line there is one call to the next line in the program, except for if-statements, where there are two calls, one for each branch to corresponding line number.

So now we get nine graphs.

Below we construct a program that give the same set of size-change graphs as given in [Jones 00] and the same call graph as the example above would give:

```
--}
```

```
boolprog =
 " f0(x1,x2,x3,x4,x5)=case x1 of
                             0->0
                             S(x1')->case x4 of
                                          0 -> 0
                                          S(x4') \rightarrow f1(x2', x2, x4', x4, S(S(x5))) \setminus
 0->0
                             S(x5') \rightarrow f2(x2, x1, x3, x4, x5')
 f2(x1,x2,x3,x4,x5) =
 \
     case x3 of
          0->0
          S(x3')->case x4 of
 \
                        0 \rightarrow (case x5 of
```

```
0 -> 0
                                  S(x5') \rightarrow f3(x1,x2,x3',x4,x5'))
